17 Questions

Given an array of integers, reverse the given array in place using an index and loop rather than a built-in function.

Example

```
arr = [1, 2, 3, 4, 5]
```

When the array [1, 4, 5, 2, 3] which is the reverse of the input array.

Function Description

Complete the function `reverseArray` in the editor below.

`reverseArray` has the following parameter(s):

- `arr` `arr` an array of integers

Returns

void: The array is reversed in place.

Constraints

- $1 \leq n \leq 100$
- $0 \leq arr[i] \leq 100$

Input Format

The first line contains an integer n , the number of elements in the array.

Each line of the n subsequent lines contains a single integer $arr[i]$.

Sample Case 0

Sample Input

```
5
1
2
3
4
5
```

Sample Output

```
5
4
3
2
1
```

Explanation

The input array is [1, 2, 3, 4, 5], so the reverse of the input array is [5, 4, 3, 2, 1].

Sample Case 1

Sample Input

```
4
12
10
21
45
```

Sample Output

```
45
21
10
12
```

Explanation

The input array is [12, 10, 21, 45], so the reverse of the input array is [45, 21, 10, 12].

Answer: (currently empty) (0 N)

17 Questions

An automated cutting machine is used to cut rods into segments. The cutting machine can only make a cut of a rod of length n into two segments of length a and b if $a + b = n$. The machine can only make one cut at a time. Given the array `lengths` representing the desired lengths of each segment, determine if it is possible to make the necessary cuts using this machine. The rod is marked into segments in the order given.

Example

```
n = 7
lengths = [4, 2, 2]
minLength = 7
```

The rod is initially segmented into 4 + 2 + 2 = 8 parts long. First cut off the segment of length 4 + 2 = 7 leaving a rod of 7 - 7 = 0. Then check that the length 7 rod can be cut into segments of length 4 and 3, since 7 is greater than or equal to min length = 7, the first cut can be made. Return "Possible".

Example

```
n = 2
lengths = [2, 2, 2]
minLength = 7
```

The rod is initially segmented into 4 + 2 + 2 = 8 parts long. In this case, the initial cut of length 4 + 2 = 6, regardless of the length of the first cut, the remaining piece will be more than min length because 7 - 1 > 0, so cannot be made, the answer is "Impossible".

Function Description

Complete the function `cutRod` in the editor below.

`cutRod` has the following parameter(s):

- `lengths` the lengths of the segments to make
- `minLength` the minimum length any machine can cut

Returns

string: "Possible" if all n rods can be made. Otherwise, return the string "Impossible".

Constraints

- $1 \leq n \leq 10^5$
- $1 \leq l \leq 10^5$
- $1 \leq minLength \leq 10^5$
- The sum of the elements of lengths equals the initial rod length.

Input Format

The first line contains an integer n , the number of elements in lengths.

Each line of the n subsequent lines contains a single integer $lengths[i]$.

The next line contains an integer, `minLength`, the minimum length required by the machine.

Sample Case 0

Sample Input

```
STDIN Function
n = 4
lengths size = 4
lengths = [1, 5, 4, 1]
4
```

Sample Output

```
Possible
```

Explanation

The initial rod is 1 + 5 + 4 + 1 = 11 units long. Cut the rod into lengths of 1 + 5 = 6 and 4. Then cut the 6 unit piece into lengths 1 and 5. The remaining segment is 1 + 5 = 6 units long and that is long enough to make the first cut.

Sample Case 1

Sample Input

```
STDIN Function
n = 5
lengths size = 5
lengths = [5, 5, 5]
5
```

Sample Output

```
Impossible
```

Explanation

The initial rod is 5 + 5 + 5 = 15 units long. After making either cut, the rod will be too short to make the desired cut.

Answer: (currently empty) (0 N)
